(Dated: November 4, 2009)

We investigate theoretically the spin states in InAs/AlSb/GaSb broken-gap quantum wells by solving the Kane model and the Poisson equation self-consistently. The spin states in InAs/AlSb/GaSb quantum wells are quite different from those obtained by the single-band Rashba model due to the electron-hole hybridization. The Rashba spin-splitting of the lowest conduction subband shows an oscillating behavior. The D'yakonov-Perel' spin relaxation time shows several peaks with increasing the Fermi wavevector. By inserting an AlSb barrier between the InAs and GaSb layers, the hybridization can be greatly reduced. Consequently, the spin orientation, the spin splitting, and the D'yakonov-Perel' spin relaxation time can be tuned significantly by changing the thickness of the AlSb barrier.

I. INTRODUCTION

Heterostructures based on InAs, GaSb, and AlSb are one of the most promising systems for fundamental physics research and design of novel devices due to their advantages of high electron mobility, narrow band gap, strong spin-orbit coupling, and more importantly, the special broken-gap band lineup at the InAs/GaSb interface^{1,2}. In the past decades, the properties of InAs/GaSb broken-gap superlattices and quantum wells (QWs) were investigated both theoretically and experimentally^{3,4,5,6,7,8,9,10,11,12,13,14}. These studies show that due to the overlap of InAs conduction band and GaSb valence band, the energy dispersion may exhibit an anticrossing behavior at a finite in-plane wave vector $k_{\parallel} \neq 0$ ^{3,4,5,6,7,8,9,10}. The tunneling between InAs and GaSb layers opens a mini hybridization gap, which was observed experimentally^{11,12,13,14}. In addition, the electrons in GaSb can move across InAs/GaSb interface into InAs layer, forming a two-dimensional electron gas in InAs side and a two-dimensional hole gas in GaSb side, which is promising for observing the Bose-Einstein condensation of excitons^{14,15,16}. In practical applications, there have been many proposals for electronic and optical devices utilizing the unique characteristics of InAs/AlSb/GaSb system such as resonant tunneling structures^{17,18}, infrared detectors¹⁹, and interband cascade laser diodes²⁰. Recently, the spin-related properties of InAs/AlSb/GaSb system also attracted much interest. For instance, there have been a number of spintronic device proposals, including the Rashba spin filter²¹, the spin field effect transistor²², and the high-frequency optical modulator utilizing the spin precession²³. Moreover, InAs/GaSb QW, like HgTe/HgCdTe QW, is another possible candidate to demonstrate the intrinsic spin Hall effect²⁴ and quantum spin Hall phase²⁵ due to the inverted band structure.

In the previous works, the electron-hole hybridization in InAs/GaSb broken-gap QWs have been well studied^{9,10,26,27}. It was shown that the "spin-up" and the "spin-down" states are affected differently by the hybridization^{9,10}. This implies that the spin states near the hybridization gap (where strong hybridization occurs) in InAs/GaSb QWs should be quite different from those in conventional semiconductor QWs. Since the Fermi level of the undoped InAs/GaSb QW lies inside the hybridization gap²⁸, the unusual spin states nearby would be

very important for many electronic properties.

In this paper, we investigate theoretically the spin orientation (i.e., the expectation value of the Pauli operator $\sigma \equiv 2\mathbf{S}$ for the electron spin $\mathbf{S}$ in an eigenstate), the zero-field spin splitting, and the D'yakonov-Perel' (DP) spin relaxation²⁹ in InAs/AlSb/GaSb QWs based on the Kane model. The charge transfer induced internal electric field is taken into account by solving the Kane model and the Poisson equation self-consistently. For InAs/AlSb/GaSb QWs, the spin orientation (or spin states) are significantly modified by the hybridization between the conduction band and valence band, which can be tuned by changing the thickness of AlSb barrier. The spin orientation can be measured indirectly from the Faraday rotation, and indeed offers us a physical picture and can lead to some novel effects such as the persistent Spin Helix³⁰. Using the grating technique and Faraday rotation, the persistent rotation of the spin orientation, i.e., spin helix of electron was observed in GaAs QW³¹. The Rashba spin-splitting (RSS) exhibits oscillating features as a function of in-plane wave vector in InAs/AlSb/GaSb QW³⁵ near the hybridization gap. The spin relaxation time, which are obtained from the perturbation theory³⁶, shows that the unusual spin-splitting could lead to several peaks with increasing the Fermi wave vector. These unusual features all come from the strong electron-hole hybridization beyond the single band model with linear Rashba spin-orbit interaction³⁷. Interestingly, the hybridization is very sensitive to the thickness of the AlSb barrier, evidenced by a rapidly decreasing hybridization gap with increasing AlSb barrier thickness. Consequently, all the spin-related properties, including the spin orientation, the spin splitting, and the DP spin relaxation time, can be tuned by varying the thickness of AlSb barrier. The property of tunable spin states in InAs/AlSb/GaSb QWs might be useful in designing new spintronic devices.

This paper is organized as follows. In Sec. II, we describe the theoretical method based on a self-consistent calculation combining the Kane model and the Poisson equation. In Sec. III, we present the numerical results for the band structure, the spin orientation, the spin-splitting and DP spin relaxation time in InAs/AlSb/GaSb QWs. In Sec. IV we give the conclusion.

II. THEORY

We consider an InAs/AlSb/GaSb broken-gap QW grown along the [001] direction [see Fig. 1 (a)]. We choose the axis x , y , and z to be along [100], [010], and [001], respectively. Within the envelope function approximation, the Kane model is a good starting point for systems with strong electron-hole hybridization like InAs/AlSb/GaSb QWs. As InAs conduction band overlaps with GaSb valence band, electrons could transfer from GaSb layer into InAs layer. The charge redistribution induces an internal electric field, which can be evaluated from the Poisson equation. Generally, one needs to know the charge density distribution to solve the Poisson equation, and the charge density distribution is in turn determined by the electron wave function. Therefore a self-consistent procedure is needed to take the charge-transfer effect into account in this system³⁸.

In Sec. II A, we discuss the Kane model and the self-consistent calculation method. To consider the spin states in broken-gap QWs, we shall give an explicit definition of “spin-up” and “spin-down” states by classifying the eigenstates of the Kane model. This is discussed in Sec. II B.

A. Hamiltonian and calculation method

Following the new envelope function theory³⁹, the Kane model which describes the bulk zinc-blende semiconductors

can be generalized to describe heterostructures by ordering the momentum operators with respect to material parameters. By choosing the following set of basis functions,

$$\phi_1 = \left| \frac{1}{2}, \frac{1}{2} \right\rangle = |S \uparrow\rangle, \quad (1a)$$

$$\phi_2 = \left| \frac{1}{2}, -\frac{1}{2} \right\rangle = |S \downarrow\rangle, \quad (1b)$$

$$\phi_3 = \left| \frac{3}{2}, \frac{3}{2} \right\rangle = \frac{1}{\sqrt{2}} |(X + iY) \uparrow\rangle, \quad (1c)$$

$$\phi_4 = \left| \frac{3}{2}, \frac{1}{2} \right\rangle = \frac{i}{\sqrt{6}} |(X + iY) \downarrow - 2Z \uparrow\rangle, \quad (1d)$$

$$\phi_5 = \left| \frac{3}{2}, -\frac{1}{2} \right\rangle = \frac{1}{\sqrt{6}} |(X - iY) \uparrow + 2Z \downarrow\rangle, \quad (1e)$$

$$\phi_6 = \left| \frac{3}{2}, -\frac{3}{2} \right\rangle = \frac{i}{\sqrt{2}} |X - iY \downarrow\rangle, \quad (1f)$$

$$\phi_7 = \left| \frac{1}{2}, \frac{1}{2} \right\rangle = \frac{1}{\sqrt{3}} |(X + iY) \downarrow + Z \uparrow\rangle, \quad (1g)$$

$$\phi_8 = \left| \frac{1}{2}, -\frac{1}{2} \right\rangle = -\frac{i}{\sqrt{3}} |(X - iY) \uparrow - Z \downarrow\rangle, \quad (1h)$$

the Kane Hamiltonian for zinc-blende crystals near the Γ point is

$$H_k = \begin{bmatrix} A & 0 & i\sqrt{3}V^\dagger & \sqrt{2}U & iV & 0 & iU & \sqrt{2}V \\ 0 & A & 0 & -V^\dagger & i\sqrt{2}U & -\sqrt{3}V & i\sqrt{2}V^\dagger & -U \\ -i\sqrt{3}V & 0 & -(P+Q) & L & M & 0 & \frac{i}{\sqrt{2}}L & -i\sqrt{2}M \\ \sqrt{2}U & -V & L^\dagger & -(P-Q) & 0 & M & i\sqrt{2}Q & i\sqrt{\frac{3}{2}}L \\ -iV^\dagger & -i\sqrt{2}U & M^\dagger & 0 & -(P-Q) & -L & -i\sqrt{\frac{3}{2}}L^\dagger & i\sqrt{2}Q \\ 0 & -\sqrt{3}V^\dagger & 0 & M^\dagger & -L^\dagger & -(P+Q) & -i\sqrt{2}M^\dagger & -\frac{i}{\sqrt{2}}L^\dagger \\ -iU & -i\sqrt{2}V & -\frac{i}{\sqrt{2}}L^\dagger & -i\sqrt{2}Q & i\sqrt{\frac{3}{2}}L & i\sqrt{2}M & -P-\Delta & 0 \\ \sqrt{2}V^\dagger & -U & i\sqrt{2}M^\dagger & -i\sqrt{\frac{3}{2}}L^\dagger & -i\sqrt{2}Q & \frac{i}{\sqrt{2}}L & 0 & -P-\Delta \end{bmatrix} \quad (1i)$$

where

$$A = E_v + E_g + \mathbf{k}A_c\mathbf{k}, \quad (2a)$$

$$P = -E_v + \frac{\hbar^2}{2m_0}\mathbf{k}\gamma_1\mathbf{k}, \quad (2b)$$

$$Q = \frac{\hbar^2}{2m_0}(k_x\gamma_2k_x + k_y\gamma_2k_y - 2k_z\gamma_2k_z), \quad (2c)$$

$$L = i\frac{\sqrt{3}\hbar^2}{m_0}\{k_- \gamma_3 k_z\}, \quad (2d)$$

$$M = -\frac{\sqrt{3}\hbar^2}{2m_0}[k_x\gamma_2k_x - k_y\gamma_2k_y - 2i\{k_x\gamma_3k_y\}], \quad (2e)$$

$$U = \frac{1}{\sqrt{3}}P_0k_z, \quad (2f)$$

$$V = \frac{1}{\sqrt{6}}P_0k_-. \quad (2g)$$

In Eq. (2), $\mathbf{k} = (\mathbf{k}_\parallel, -i\partial/\partial_z)$, $k_\pm = k_x \pm ik_y$, and $\{k_\alpha\gamma k_\beta\} = (k_\alpha\gamma k_\beta + k_\beta\gamma k_\alpha)/2$ ($\alpha, \beta = x, y, z$). Here the in-plane momentum as a constant of motion has been replaced by its eigenvalue $\mathbf{k}_\parallel$ and we have neglected the bulk inversion asymmetry (Dresselhaus effect) since it is small compared to the structure inversion asymmetry (Rashba effect). The strain effect is also neglected because the lattice mismatch between InAs and GaSb is less than 1%.

TABLE I: The Kane parameters used in our calculation. These parameters are calculated from the Luttinger parameters obtained from Ref. 40 (see the formulism below Table I). The value of Kane energy $E_p = 2m_0P_0^2/\hbar^2$ is taken equal to 22.5 eV for each layer material.

	InAs	GaSb	AlSb
E_g (eV)	0.417	0.812	2.386
E_v (eV)	-0.417	0.143	-0.237
Δ (eV)	0.39	0.76	0.676
A_c (eV·nm ²)	-0.26	0.09	-0.06
γ_1	2.01	4.16	2.04
γ_2	-0.49	8.18	-0.38
γ_3	0.21	1.38	0.40
ε	14.55	15.69	14.4

^aThe relation between Kane parameters and Luttinger parameters are $\gamma_1 = \gamma_1^L - \frac{E_p}{3E_g}$, $\gamma_2 = \gamma_2^L - \frac{E_p}{6E_g}$, $\gamma_3 = \gamma_3^L - \frac{E_p}{6E_g}$.

^b A_c is correlated to electron effective mass m^* by $A_c = \frac{\hbar^2}{2m^*} - \frac{E_p}{6m_0}(\frac{2}{E_g} + \frac{1}{E_g + \Delta})$.

The band parameters are assumed to be a piecewise function along the growth direction,

$$\gamma(z) = \sum_i \gamma^i [\Theta(z - z_i) - \Theta(z - z_{i+1})], \quad (3)$$

where $\Theta(z)$ is the Heaviside step function, z_i is the i -th interface of this system, and γ^i is the bulk band parameters of the i -th layer. These band parameters, including E_g , E_v , Δ , A_c , γ_1 , γ_2 , and γ_3 , can be derived from the Luttinger parameters and the electron effective mass⁴⁰. They are given in table I. The valence band offset of two neighboring materials is $\Delta E_v^i = E_v^i - E_v^{i+1}$.

For thick enough InAs and GaSb layers, the lowest conduction subband in InAs layer overlaps with the highest valence subband in GaSb layer. Electrons could transfer from GaSb to InAs, inducing an internal electrostatic potential $V_{in}(z)$. Therefore, the total Hamiltonian becomes $H(\mathbf{k}_{\parallel}) = H_k(\mathbf{k}_{\parallel}) - eV_{in}(z)$. The subband dispersions and the corresponding eigenstates are obtained from the Schrödinger equation

$$H(\mathbf{k}_{\parallel}) |\Psi_s(\mathbf{k}_{\parallel})\rangle = E_s(\mathbf{k}_{\parallel}) |\Psi_s(\mathbf{k}_{\parallel})\rangle, \quad (4)$$

where s is the index of the subband and $|\Psi_s(\mathbf{k}_{\parallel})\rangle = \exp(i\mathbf{k}_{\parallel} \cdot \boldsymbol{\rho}) [\varphi_1^s(z), \varphi_2^s(z), \dots, \varphi_8^s(z)]^T$ is the envelope function. To solve the Schrödinger equation, we expand φ_n^s by a series of plane waves,

$$\varphi_n^s(z) = \frac{1}{\sqrt{L}} \sum_{m=-N}^N c_{nm}^s \exp(ik_m z), \quad (5)$$

where $k_m = 2m\pi/L$ and L is the total length of the structure (in this work, $L = 2L_{AlSb}^{side} + L_{InAs} + L_{AlSb}^{middle} + L_{GaSb}$, and $L_{AlSb}^{side} = 2L_{InAs}$). By choosing a moderate N , one can also avoid the spurious solutions that may occur in the Kane model.⁴¹ In our calculation, $N \approx 25$ is good enough to get convergent results.

The internal electrostatic potential $V_{in}(z)$ is determined by the Poisson equation

$$\frac{d}{dz} \varepsilon(z) \frac{d}{dz} V_{in}(z) = -[\rho_e(z) + \rho_h(z)], \quad (6)$$

where $\rho_e(z)$ and $\rho_h(z)$ are, respectively, the charge density due to electrons and holes and $\varepsilon(z)$ is the static dielectric constant. $\rho_e(z)$ and $\rho_h(z)$ can be derived from the envelope functions:

$$\rho_e(z) = -\frac{e}{(2\pi)^2} \sum_s \int \sum_{n=1,2} |\varphi_n^s(z)|^2 f_F(E_s) d\mathbf{k}_{\parallel}, \quad (7)$$

$$\rho_h(z) = \frac{e}{(2\pi)^2} \sum_s \int \sum_{n=3,4,\dots,8} |\varphi_n^s(z)|^2 [1 - f_F(E_s)] d\mathbf{k}_{\parallel}, \quad (8)$$

where $f_F(E_s)$ is the Fermi distribution function. The summations $\sum_{n=1,2}$ and $\sum_{n=3,4,\dots,8}$ runs over the electron components ϕ_1, ϕ_2 and hole components $\phi_3, \dots, \phi_8$ respectively. The summation $\sum_s$ includes all the subbands which show anticrossing behavior. For simplicity, we take $T = 0$ K and the axial approximation^{32,33} in the self-consistent procedure. Since we want to give a clear picture about the effect of the hybridization on the spin states, we only consider the anticrossing occurs when the lowest conduction subband meets the highest valence subband, which limits to the two cases $L_{InAs} \leq 14$ nm at $L_{GaSb} = 10$ nm and $L_{GaSb} \leq 14$ nm at $L_{InAs} = 10$ nm.

The Fermi level E_F is determined by the charge neutrality condition.

$$\int_0^L [\rho_e(z) + \rho_h(z)] dz = 0. \quad (9)$$

The Fermi level E_F obtained by Eqs. (7)-(9) locates closely above the mini gap^{28,34}. Combining Eqs. (4)-(9), we can do a self-consistent iteration that eventually yields the internal electrostatic potential $V_{in}(z)$. Once we have $V_{in}(z)$, the subband dispersions and electronic states can be obtained by solving Eq. (4).

B. The classification of the spin states

In the single-band Rashba model for the electron (i.e., ϕ_1 and ϕ_2 components only), there is a well-defined spin quantization axis $\hat{\mathbf{e}}_{\Sigma} = \hat{\mathbf{e}}_{\mathbf{k}_{\parallel}} \times \hat{\mathbf{e}}_z$ perpendicular to both the wave vector direction $\hat{\mathbf{e}}_{\mathbf{k}_{\parallel}}$ and the QW growth direction $\hat{\mathbf{e}}_z$. The spin orientation of any eigenstate always has a magnitude of unity and is either parallel (called “spin-up” eigenstates) or anti-parallel (called “spin-down” eigenstates) to $\hat{\mathbf{e}}_{\Sigma}$ ⁴². For the $J = 3/2$ hole system (i.e., components $\phi_3, \dots, \phi_6$) or a hybridized electron-hole system⁴³, however, such a quantization axis does not exist. As we shall show in Sec. III, for a given conduction subband, the spin orientation may change its magnitude and direction (up to 180 degrees) with increasing $\mathbf{k}_{\parallel}$. The absence of a well-defined spin quantization axis make it impossible to classify the “spin-up” and “spin-down” states by their spin orientations relative to this quantization axis.

In the following, we divide the Kane Hamiltonian $H_k(\mathbf{k}_{\parallel})$ in Eq. (11) (note that bulk inversion asymmetry has been

neglected) as the sum of a dominating part $H_{ax}(\mathbf{k}_{\parallel})$ with axial symmetry and a small cubic part $H_{cub}(\mathbf{k}_{\parallel})$ with cubic symmetry⁴⁴

$$H_k(\mathbf{k}_{\parallel}) = H_{ax}(\mathbf{k}_{\parallel}) + H_{cub}(\mathbf{k}_{\parallel}). \quad (10)$$

The axial part $H_{ax}(\mathbf{k}_{\parallel})$ obtained from Eq. (1i) by replacing γ_2 and γ_3 with $\bar{\gamma}$ in the term M and the cubic part $H_{cub}(\mathbf{k}_{\parallel}) \equiv H_k(\mathbf{k}_{\parallel}) - H_{ax}(\mathbf{k}_{\parallel})$ is the difference between $H_k(\mathbf{k}_{\parallel})$ and $H_{ax}(\mathbf{k}_{\parallel})$.

The axial part $H_{ax}(\mathbf{k}_{\parallel})$ can be transformed into a block-diagonal form by choosing a new basis set. Similar transformation has been reported in dealing with the four-band³² and six-band models³³, but the cubic part was neglected in these works. In this paper the transformation is extended to the eight-band model and the cubic part is also included. Let $\mathbf{k}_{\parallel} = k_{\parallel}(\cos \varphi, \sin \varphi)$ and the new basis set is φ -dependent,

$$\begin{aligned} |S(-)\rangle &= \frac{1}{\sqrt{2}}(i\phi_1 - e^{i\varphi}\phi_2), & |S(+)\rangle &= \frac{1}{\sqrt{2}}(i\phi_1 + e^{i\varphi}\phi_2), \\ |HH(-)\rangle &= \frac{e^{-i\varphi}}{\sqrt{2}}(\phi_3 + e^{3i\varphi}\phi_6), & |HH(+)\rangle &= \frac{e^{-i\varphi}}{\sqrt{2}}(\phi_3 - e^{3i\varphi}\phi_6), \\ |LH(-)\rangle &= \frac{1}{\sqrt{2}}(\phi_4 + e^{i\varphi}\phi_5), & |LH(+)\rangle &= \frac{1}{\sqrt{2}}(\phi_4 - e^{i\varphi}\phi_5), \\ |SO(-)\rangle &= \frac{i}{\sqrt{2}}(\phi_7 + e^{i\varphi}\phi_8), & |SO(+)\rangle &= \frac{i}{\sqrt{2}}(\phi_7 - e^{i\varphi}\phi_8), \end{aligned} \quad (11)$$

Under this basis, $H_{ax}(\mathbf{k}_{\parallel}) \rightarrow \mathcal{H}_{ax}(k_{\parallel})$ is block-diagonalized and $H_{cub}(\mathbf{k}_{\parallel}) \rightarrow \mathcal{H}_{cub}(k_{\parallel})$ has a simple dependence on the azimuth φ ,

$$\mathcal{H}_{ax}(k_{\parallel}) = \begin{pmatrix} \mathcal{H}_-(k_{\parallel}) & 0 \\ 0 & \mathcal{H}_+(k_{\parallel}) \end{pmatrix}, \quad (12)$$

$$\mathcal{H}_{cub}(\mathbf{k}_{\parallel}) = \begin{pmatrix} \mathcal{A}(k_{\parallel}) \cos 4\varphi & -i\mathcal{A}(k_{\parallel}) \sin 4\varphi \\ i\mathcal{A}(k_{\parallel}) \sin 4\varphi & -\mathcal{A}(k_{\parallel}) \cos 4\varphi \end{pmatrix}, \quad (13)$$

where

$$\mathcal{H}_{\pm}(k_{\parallel}) = \begin{bmatrix} A & \sqrt{3}V' & -\sqrt{2}U' \mp V' & U' \mp \sqrt{2}V' \\ \sqrt{3}V' & -P - Q & L' \mp M' & -\frac{L' \pm 2M'}{\sqrt{2}} \\ \sqrt{2}U' \mp V' & -L' \mp M' & -P + Q & -\frac{2Q \pm \sqrt{3}L'}{\sqrt{2}} \\ -U' \mp \sqrt{2}V' & \frac{L' \mp 2M'}{\sqrt{2}} & -\frac{2Q \mp \sqrt{3}L'}{\sqrt{2}} & -P - \Delta \end{bmatrix}, \quad (14)$$

$$\mathcal{A}(k_{\parallel}) = \frac{\sqrt{3}\hbar^2 k_{\parallel}^2}{2m_0} \Delta \bar{\gamma} \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & \sqrt{2} \\ 0 & 1 & 0 & 0 \\ 0 & \sqrt{2} & 0 & 0 \end{bmatrix}, \quad (15)$$

and

$$L' = i\frac{\sqrt{3}\hbar^2}{2m_0}k_{\parallel}(\gamma_3 k_z + k_z \gamma_3), \quad (16a)$$

$$M' = -\frac{\sqrt{3}\hbar^2}{2m_0}\bar{\gamma}k_{\parallel}^2, \quad (16b)$$

$$U' = \frac{i}{\sqrt{3}}P_0 k_z, \quad (16c)$$

$$V' = \frac{1}{\sqrt{6}}P_0 k_{\parallel}, \quad (16d)$$

$$\bar{\gamma} = \frac{1}{2}(\gamma_2 + \gamma_3), \quad (16e)$$

$$\Delta \bar{\gamma} = \frac{1}{2}(\gamma_2 - \gamma_3). \quad (16f)$$

Using the new basis set, we can give an explicit classification of all the eigenstates into “spin-up” and “spin-down” states, similar to the single-band model.

In the absence of the cubic term $\mathcal{H}_{cub}(\mathbf{k}_{\parallel})$ (so-called axial approximation), the eigenstates $|\Psi_{s,\pm}^{(ax)}(k_{\parallel})\rangle$ and eigen-energies $E_{s,\pm}^{(ax)}(k_{\parallel})$ (for the s -th subband) of the total Hamiltonian $H(\mathbf{k}_{\parallel}) = \mathcal{H}_{ax}(k_{\parallel}) - eV_{in}(z)$ are determined by

$$[\mathcal{H}_{\pm}(k_{\parallel}) - eV_{in}(z)]|\Psi_{s,\pm}^{(ax)}(k_{\parallel})\rangle = E_{s,\pm}^{(ax)}(k_{\parallel})|\Psi_{s,\pm}^{(ax)}(k_{\parallel})\rangle, \quad (17)$$

with the Rashba spin splitting in the s -th subband

$$\Delta E_s^{(ax)}(k_{\parallel}) = E_{s,+}^{(ax)}(k_{\parallel}) - E_{s,-}^{(ax)}(k_{\parallel}). \quad (18)$$

Obviously, the eigenstates are automatically classified into two classes: the “spin-down” states $|\Psi_{s,-}^{(ax)}(k_{\parallel})\rangle$ consisting of the components $|S(-)\rangle$, $|HH(-)\rangle$, $|LH(-)\rangle$, and $|SO(-)\rangle$ and the “spin-up” states $|\Psi_{s,+}^{(ax)}(k_{\parallel})\rangle$ consisting of the components $|S(+)\rangle$, $|HH(+)\rangle$, $|LH(+)\rangle$, and $|SO(+)\rangle$. Then one can define the spin orientation of an arbitrary eigenstate $|\Psi_{s,\pm}^{(ax)}(k_{\parallel})\rangle$ as^{42,43}

$$\langle \Sigma^{(ax)}(\mathbf{k}_{\parallel}) \rangle_{s,\pm} = \langle \Psi_{s,\pm}^{(ax)}(k_{\parallel}) | \Sigma(\varphi) | \Psi_{s,\pm}^{(ax)}(k_{\parallel}) \rangle, \quad (19)$$

where $\Sigma(\varphi) \equiv [\Sigma_x(\varphi), \Sigma_y(\varphi), \Sigma_z(\varphi)]$ are 8×8 matrices (see Appendix A) for the Pauli operators $\sigma \equiv 2S$ in the new basis (11).

In the presence of the cubic part $\mathcal{H}_{cub}(\mathbf{k}_{\parallel})$, the off-block-diagonal terms $\pm i\mathcal{A} \sin 4\varphi$ will in general couple the “spin-up” states with “spin-down” states, unless $\mathbf{k}_{\parallel}$ points along a high symmetry axis satisfying $\sin 4\varphi = 0$. As a result, the exact eigenstate $|\Psi_s(\mathbf{k}_{\parallel})\rangle$ of the Kane Hamiltonian is in general a mixture of “spin-up” and “spin-down” states. For convenience, however, we still classify the exact eigenstates as “spin-up” or “spin-down” states according to the dominant component.

Now we discuss the electronic structure of InAs/GaSb and InAs/AlSb/GaSb QWs in the axial approximation [$\mathcal{H}_{cub}(\mathbf{k}_{\parallel}) = 0$] and the modification due to the cubic correction $\mathcal{H}_{cub}(\mathbf{k}_{\parallel})$. In the axial approximation, the electronic structure shows three distinct features:

1. Electron-hole anticrossing. If the InAs and GaSb layers are thick enough, the lowest conduction subband (*CB1*) anticrosses with the highest valence subband (*VB1*) at a critical in-plane wave vector k_a , evidenced by the switch of the dominant component (a) from $|HH(\pm)\rangle$ to $|S(\pm)\rangle$ for the *CB1* subband state $|\Psi_{CB1,\pm}^{(ax)}(k_{\parallel})\rangle$ and (b) from $|S(\pm)\rangle$ to $|HH(\pm)\rangle$ for the *VB1* subband state $|\Psi_{VB1,\pm}^{(ax)}(k_{\parallel})\rangle$ when $k_{\parallel}$ is increased across k_a .
2. The spin orientation of $|\Psi_{s,\pm}^{(ax)}(k_{\parallel})\rangle$ is always along $\hat{e}_{\Sigma} = \hat{e}_{k_{\parallel}} \times \hat{e}_z$, i.e., in the QW plane and perpendicular to the in-plane wave vector $k_{\parallel}$, in agreement with the prescription of the single-band Rashba model^{37,42} (this can be verified using Eqs. (A8a)-(A9c) in Appendix A). But the projection of the spin orientation varies with $k_{\parallel}$ and may even change sign, which is different from the single-band Rashba model.
3. The Rashba spin-splitting of the *CB1* subband exhibits an oscillating behavior [containing zero spin-splitting (spin degeneracy) points] due to the electron-hole anticrossing.

In the presence of the cubic correction $\mathcal{H}_{cub}(k_{\parallel})$, the following additional features are introduced:

1. The band structure and spin-splitting as a function of $k_{\parallel}$ display a C_{4v} symmetry.
2. The spin orientation of the exact eigenstate $|\Psi_s(k_{\parallel})\rangle$ deviates from $\hat{e}_{\Sigma} = \hat{e}_{k_{\parallel}} \times \hat{e}_z$ (although it still lies in the QW plane) due to hybridization of spin-up and spin-down states. The maximum deviation arises when the azimuth angle φ of $k_{\parallel}$ satisfies $\sin(4\varphi) = \pm 1$ [such that the spin mixing matrix element in Eq. (13) reaches the maximum] and at one of the spin degeneracy points.

In Sec. III, all these special properties in InAs/GaSb and InAs/AlSb/GaSb broken-gap QWs are demonstrated by our numerical results.

III. NUMERICAL RESULTS AND DISCUSSION

In Fig. 1 we show the self-consistent band profile of an InAs/AlSb/GaSb broken-gap QWs. In this QW, the concentration of electrons transferred from GaSb layer to InAs layer is found to be of the order $1.61 \times 10^{11} \text{ cm}^{-2}$. The resulting electrostatic potential $V_{in}(z)$ induces a 8~14 meV downward (upward) bending of the InAs conduction band (GaSb valence band) near the interface and causes a slight shift of the subbands (see Fig. 1 (b)). Note that we denote the upper two branches of anticrossed subbands as *CB1*($\pm$) and the lower two as *VB1*($\pm$) (see Fig. 2), which are different from the previous works^{9,10}.

In Fig. 2 we plot the band structure of InAs/AlSb/GaSb QWs with different thicknesses of middle AlSb barrier (The thicknesses of InAs and GaSb layers are fixed at 10 nm). Due to electron-hole hybridization, the *CB1* and *VB1* subbands exhibit a strong anticrossing behavior and open a mini

FIG. 1: (Colour online) (a) Band profile and the probability density distribution of *CB1*($\pm$) (blue line), *VB1*($\pm$) (red line) states in a 10-2-10 nm InAs/AlSb/GaSb quantum well at $k_{\parallel} = 0$; (b) the amplification of the dashed square area in panel (a). The black solid, blue dashed, red dashdot and green dotted line in panel (b) denotes the results of $L_{AlSb} = 0 \text{ nm}, 1 \text{ nm}, 2 \text{ nm}$ and 5 nm respectively.

FIG. 2: (Colour online) The subband dispersions of InAs/AlSb/GaSb quantum well structures with different thicknesses of AlSb layers: (a) $L_{AlSb} = 0$ (b) $L_{AlSb} = 1 \text{ nm}$ (c) $L_{AlSb} = 2 \text{ nm}$ (d) $L_{AlSb} = 5 \text{ nm}$. The thicknesses of InAs and GaSb layers are fixed at 10 nm. The Fermi energy denoted by the dashed lines lies at the bottom of the lowest conduction band, in agreement with previous works^{3,28}. In panel (a) and (c), the cross points between *CB1* (*VB1*) and the purple (green) dashed-dotted lines mark the constant energy contours drawn in Fig. 3 (Fig. 4).

hybridization gap at a finite $k_{\parallel}$, consistent with the previous works^{5,6,7,8,9,10}. The resulting strongly-hybridized states near the gap may have significant contributions to the spin-related properties of the broken-gap QWs, since the Fermi energy (the dashed lines in Fig. 2) locates nearby^{28,34}. From Fig. 2 (b)-(d), we can see that by increasing the thickness of the AlSb barrier layer, the anticrossing between *CB1* and *VB1* is gradually weakened and the hybridized gap is noticeably narrowed due to the tunneling between *CB1* and *VB1* is sup-

FIG. 3: (Colour online) The spin orientations on the constant energy contours of $CB1(+)$ subband of (a) a 10 nm InAs/10 nm GaSb QW; (b) a 10 nm InAs/2 nm AlSb/10 nm GaSb QW. Note the dominant components of the states of the insidest contours are $|HH(+)\rangle$, while that of the other contours are $|S(+)\rangle$.

pressed significantly. Meanwhile, the spin splitting of each subband is greatly reduced due to the decreasing structural inversion asymmetry in the InAs/AlSb/GaSb QW compared with the InAs/GaSb QW.

In Fig. 3 (a) we show the spin orientations of the eigenstates on different constant energy contours of $CB1(+)$ subband in InAs/GaSb QW. The spin orientations on the contour of $CB1(-)$ subband are antiparallel to those of $CB1(+)$ subband and are omitted in the figure for brevity. In the k -

FIG. 4: (Colour Online) The spin orientations on the constant energy contours of $VB1$ subband of (a) a 10 nm InAs/10 nm GaSb QW; (b) a 10 nm InAs/2 nm AlSb/10 nm GaSb QW. The blue and red lines represent $VB1(+)$ and $VB1(-)$ branches respectively.

linear Rashba model, the spin orientations of an eigenstate is along $\hat{e}_\Sigma = \hat{e}_{k_\parallel} \times \hat{e}_z$, i.e., along the tangent direction of the circular energy contour in the QW plane⁴². However, this property no longer holds for InAs/AlSb/GaSb broken-gap QW. The spin orientations deviate strongly from the tangent direction $\hat{e}_{k_\parallel} \times \hat{e}_z$, unless $k_\parallel$ points along high symmetry directions (such as $\langle 100 \rangle$ and $\langle 110 \rangle$) satisfying $\sin 4\varphi = 0$. This comes from the hybridization between the “spin-up” and “spin-down” states, as discussed in the previous section. Therefore we can see the spin orientations on the contour

FIG. 5: (Colour online) The components of states in $CB1(\pm)$ subband as a function of $k_{||}$ along $\varphi = \pi/8$ (solid line) and $\varphi = \pi/4$ ([110]) direction (dashed line) in a 10 nm InAs/10 nm GaSb QW (a), (b) and a 10 nm InAs/2 nm AlSb/10 nm GaSb QW (c), (d). The red arrows indicate the maximum hybridization point.

$E = 130$ meV deviate the most heavily because this contour is nearest to the maximum hybridization point, and when $k_{||}$ lies in the directions $\varphi = \pi/8, 3\pi/8$ ($\sin 4\varphi = \pm 1$), the maximum hybridization occurs. When we insert an AlSb barrier between InAs and GaSb layers, the hybridization is strongly reduced [Fig. 3(b)]. Thus the deviation of the spin orientation from the tangent direction is very small. The results of Fig. 3 imply that one can tune the spin orientations near the Fermi level by changing the thickness of AlSb barrier in the middle of InAs and GaSb layers.

Fig. 4 (a) exhibits the spin orientations for the states on different constant energy contours of VB1 subband in a InAs/GaSb QW. The energy contours of VB1 subband show a very complicated behavior and a strong anisotropy in [100] and [110] directions due to the complicated band structures (see Fig. 2). From the figure, one can easily find a C_{4v} group symmetry, which comes from cubic symmetry of the crystal. For $E = 113$ meV, we can find two pairs of contours. The states are electron-like for the inner but hole-like for the outer pair. Due to the large spin splitting, the shape of energy contour for “spin-up” and “spin-down” state looks very different. If we insert an AlSb barrier between InAs and GaSb layers, the spin-splitting between VB1(+) and VB1(−) is greatly reduced (see Fig. 4 (b)).

In order to demonstrate the hybridization of the “spin-up” and “spin-down” state, we plot the components $|S(\pm)\rangle$, $|HH(\pm)\rangle$, $|LH(\pm)\rangle$ of states in $CB1(\pm)$ subbands in Fig. 5. From this figure, one can see that the components $|HH(\pm)\rangle$ and $|S(\pm)\rangle$ varies significantly when increase $k_{||}$ over the anticrossing point k_a ^{9,10,35}. Interestingly, at $\varphi = \pi/8$ direction, a strong hybridization between the “spin-up” state and “spin-down” state in the $CB1$ subbands occurs. This feature can be proven by the peak of “spin-down” component and the dip of

FIG. 6: (Colour online) The projection of spin expectation values of $|\Psi_{CB1,\pm}\rangle$ and $|\Psi_{VB1,\pm}\rangle$ states along the orthogonal direction of $k_{||}$ in InAs/AlSb/GaSb quantum well structures with different thicknesses of AlSb layers: (a) $L_{AISb} = 0$ (b) $L_{AISb} = 1$ nm (c) $L_{AISb} = 2$ nm (d) $L_{AISb} = 5$ nm. The thickness of InAs and GaSb layers are fixed at 10 nm.

“spin-up” component at $k_{||} = 0.145 \text{ nm}^{-1}$ in the $CB1(+)$ subband. A similar behavior appears in the $CB1(-)$ subband. For $k_{||}$ along [110] ($\sin(4\varphi) = 0$), there is no hybridization in the $CB1$ subbands and leading to pure “spin-up” and “spin-down” states. By inserting an AlSb barrier between InAs and GaSb layers, the hole-like to electron-like transition of $|\Psi_{CB1,\pm}\rangle$ states become more emergent, and the hybridization between “spin-up” or “spin-down” state is reduced.

As a result of the dominant component transition of the $|\Psi_{CB1,\pm}\rangle$ and $|\Psi_{VB1,\pm}\rangle$ states when $k_{||}$ sweeps across the anticrossing point k_a , the spin expectation value magnitude $\langle \Sigma \rangle$ change correspondingly. In Fig. (6) we display the change of $\langle \Sigma \rangle$ for $|\Psi_{CB1,\pm}\rangle$ and $|\Psi_{VB1,\pm}\rangle$ states as a function of $k_{||}$. $\langle \Sigma \rangle$ can be defined by projecting the vector $\langle \Sigma \rangle$ onto $\hat{e}_\Sigma$, with $\hat{e}_\Sigma = \hat{e}_{k_{||}} \times \hat{e}_z$ is the unit vector of the in-plane direction perpendicular to $k_{||}$. A sudden change of $\langle \Sigma \rangle$ appears in Fig. (6) when $k_{||}$ sweeps across the anticrossing point k_a so that the main characteristic of $|\Psi_{CB1,\pm}\rangle$ ($|\Psi_{VB1,\pm}\rangle$) states change from hole-like (electron-like) to electron-like (hole-like). In addition, we find sign reversals occur for $\langle \Sigma \rangle$ near the anticrossing points, which means the spin orientations do not maintain the same direction. This leads to the failure of recognizing the “spin-up” and “spin-down” branches simply by their spin orientations. Therefore we should classify the different spin states in a new set of basis functions as discussed in Sec. II B. Increasing the thickness of middle AlSb barrier, i.e., weakening of the interlayer coupling between InAs and GaSb layers, makes the smooth variation of $\langle \Sigma \rangle$ more and more sharp.

Besides the spin orientations in InAs/AlSb/GaSb QWs, it is interesting to discuss the zero-field spin-splitting in these QWs because it can be directly measured from the experiments⁴⁵. Therefore, we plot the Rashba spin-splitting

FIG. 7: (Colour online) Rashba spin-splitting of *CB1* (blue line) and *VB1* (red line) subbands in InAs/AlSb/GaSb quantum well structures with different thicknesses of AlSb layers: (a) $L_{\text{AlSb}} = 0$ (b) $L_{\text{AlSb}} = 1$ nm (c) $L_{\text{AlSb}} = 2$ nm (d) $L_{\text{AlSb}} = 5$ nm. The thickness of InAs and GaSb layers are fixed at 10 nm. The red arrows mark the cross point between the curve of RSS and the dashdotted line $\Delta E = 0$.

(RSS) of *CB1* and *VB1* subbands as a function of the in-plane momentum in Fig. 7 (a). From the figure, one can see a valley and sign-reversal occurs in the RSS of *CB1* subband, leading to the oscillating behavior. This anomalous behavior arises from the difference between the anticrossing point between the *CB1*(+) and *VB1*(+) subbands and that between the *CB1*(-) and *VB1*(-) subbands. The decrease of RSS appearing at large $k_{||}$ is caused by the weakening of the conduction-valence band-coupling for carriers with large momentum, i.e., large kinetic energy or large effective bandgap⁴⁶. In Fig. 7, we have marked the $\Delta E = 0$ (spin degeneracy) points with red arrows. By comparing to Fig. 5, we find these points actually lead to the maximum hybridized points in Fig. 5. The splitting of *VB1* subband is much larger than that of *CB1* subband. This reflects the fact that the spin-orbit coupling in valence band is much stronger than that of conduction band. An extremum appears in the RSS of *VB1* subband near the anticrossing point. Fig. 7 (b)-(d) shows the RSS of QWs with a AlSb barrier inserted between InAs and GaSb layers. When introducing an AlSb barrier into InAs/GaSb QW, the asymmetry at the left and right interfaces for InAs and GaSb layers is compensated, so the RSS of InAs/AlSb/GaSb QWs decreases greatly with increasing the thickness of AlSb layer. The valley in RSS of *CB1* subband becomes sharper because the anticrossing behavior between the *CB1* and *VB1* subbands is heavily weakened as the AlSb barrier thickness increases. Interestingly, the anticrossing behavior seems like a crossing for the thick middle AlSb barrier, e.g., $L_{\text{AlSb}} = 5$ nm.

Since the spin-splitting and spin states in InAs/GaSb and InAs/AlSb/GaSb broken-gap QWs are very different from that in conventional semiconductor QWs, the spin-related properties in these QWs should manifest a distinct feature as a con-

FIG. 8: (Colour online) Dyakonov-Perel spin relaxation time of *CB1* subband as a function of Fermi wave vector k_F in InAs/AlSb/GaSb QWs with different thicknesses of AlSb layers: (a) $L_{\text{AlSb}} = 0$ (b) $L_{\text{AlSb}} = 1$ nm (c) $L_{\text{AlSb}} = 2$ nm (d) $L_{\text{AlSb}} = 5$ nm. The red arrows mark the resonant peaks corresponding to the spin-degeneracy points.

sequence. As an example, the DP spin relaxation time of *CB1* subband in InAs/GaSb and InAs/AlSb/GaSb broken-gap QWs is calculated by taking axial approximation and based on the perturbation theory³⁶. This theory demonstrates that the DP spin relaxation rate $\tau_z^{-1} \propto \Omega^2 \propto (\Delta E_{\text{CB1}}^{\text{ax}})^2$, where Ω is the spin-orbit coupling induced in-plane effective magnetic field and proportional to the spin splitting $\Delta E_{\text{CB1}}^{\text{ax}}$. The perturbation theory gives a clear physical picture about the DP spin relaxation, that the DP spin relaxation time would show resonant peaks when the spin splitting vanishes. As shown in Fig. 8, for a momentum relaxation time $\tau_p = 0.1$ ps, we find the DP spin relaxation time in these QWs varies from 1 ps to 10^5 ps with different k_F , and the DP spin relaxation time τ_z exhibits an obvious oscillating behavior. The resonant peaks (marked with the red arrows), actually corresponds to the $\Delta E = 0$ in (spin degeneracy) points Fig. 7. From panel (a)-(d), we can see the spin relaxation time in InAs/AlSb/GaSb QWs is very sensitive to the thicknesses of middle AlSb layer. The oscillating and large-scale variation features of DP spin relaxation time in InAs/GaSb/AlSb QWs are dramatically different from that in conventional semiconductor QWs. We suppose the unique features of spin relaxation time InAs/GaSb/AlSb broken-gap QWs could provide us an interesting way to manipulate the evolution of electron spins.

In Fig. 9 we show the mini gap as a function of the thickness of the middle AlSb barrier in InAs/AlSb/GaSb QWs. The mini gap describes the degree of electron-hole hybridization. Fix the thickness of InAs and GaSb layer of InAs/AlSb/GaSb QW and increase the thickness of middle AlSb barrier, the mini gap decrease rapidly, this feature was already demonstrated experimentally in Ref. 14, in which a 1.75 meV mini gap has been measured for a 15 nm-10 nm InAs/GaSb QW and a 1.75 meV mini gap for a 15 nm-1.5 nm-15 nm

FIG. 9: Mini gap as a function of the thickness of AlSb barrier in InAs/AlSb/GaSb QWs with (a) L_{GaSb} fixed at 10 nm, (b) L_{InAs} fixed at 10 nm.

InAs/AlSb/GaSb QW. The mini gap measured from the experiments in Refs.11,12,13, are 4, 7 and 2 meV respectively. Based on our calculation, the mini gap is found to be 0~4 meV, the order agree with the experiments. In general, we can see the mini gaps reduce to zero when the thickness of the AlSb barrier become larger than 5 nm. This is because the tunneling between InAs conduction band and GaSb valence band is greatly suppressed by the AlSb barrier, so the electron-hole hybridization is restricted. In addition, if we fix AlSb barrier, and increase the thickness of InAs layer or AlSb layer, the mini gap decrease too. This is because the confining energy is reduced as the thickness of InAs layer or AlSb layers increases, and the anticrossing point is then moved towards a higher $k_{\parallel}$, which has less conduction-valence interband coupling strength and forms a smaller mini gap. As the mini gap and the hybridization degree change, the spin-related properties, including the spin orientations, spin splitting, and DP spin relaxation time change consequently. Therefore we certainly find a method to tune the spin states in InAs/AlSb/GaSb QWs, which might be taken advantages in designing spintronic devices.

IV. CONCLUSION

We have investigated theoretically the spin orientation, spin-splitting, spin relaxation in InAs/AlSb/GaSb broken-gap QWs. We found the spin states in these broken-gap QWs are very different from that in conventional semiconductor QWs. The spin orientations deviate away from the tangent direction of the energy constant surface and the RSS of the anticrossed CB1 subband in InAs/AlSb/GaSb QWs exhibits a nonlinear and oscillating behavior. The deviation of spin orientation comes from the strong hybridization between different spin states, and the oscillating behavior of RSS is a result of the anticrossing of energy dispersions according. The distinct properties of RSS in InAs/AlSb/GaSb QWs lead to an oscillating behavior of DP spin relaxation time obtained from the perturbation theory. By changing the thickness of AlSb barrier

between the InAs and GaSb layers, the degree of hybridization can be tuned heavily, the mini hybridization gap and spin orientations on the Fermi surface can be changed as a consequence. Our theoretical calculation is interesting both from the basic physics and potential application of the spintronic devices based on this novel broken-gap semiconductor QW system.

APPENDIX A: EIGHT-BAND SPIN MATRICES

Following the derivation of R. Winkler⁴², we can obtain the form of eight-band spin matrices vector in the basis set (1h) by $\Sigma' = \sigma \otimes \mathbb{L}_{orb}$, where $\sigma = (\sigma_x, \sigma_y, \sigma_z)$ is the vector of Pauli spin matrices, and $\mathbb{L}_{orb}$ refers to the orbital part of the set basis function (1h). The components $\Sigma'_x, \Sigma'_y, \Sigma'_z$ of Σ' can be written as:

$$\Sigma'_x = \begin{bmatrix} 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & \frac{i}{\sqrt{3}} & 0 & 0 & \frac{\sqrt{6}}{3} & 0 \\ 0 & 0 & -\frac{i}{\sqrt{3}} & 0 & \frac{2}{3}i & 0 & 0 & -\frac{\sqrt{2}}{3} \\ 0 & 0 & 0 & -\frac{2}{3}i & 0 & \frac{i}{\sqrt{3}} & \frac{\sqrt{2}}{3} & 0 \\ 0 & 0 & 0 & 0 & -\frac{i}{\sqrt{3}} & 0 & 0 & -\frac{\sqrt{6}}{3} \\ 0 & 0 & \frac{\sqrt{6}}{3} & 0 & \frac{\sqrt{2}}{3} & 0 & 0 & \frac{1}{3}i \\ 0 & 0 & 0 & -\frac{\sqrt{2}}{3} & 0 & -\frac{\sqrt{6}}{3} & -\frac{1}{3}i & 0 \end{bmatrix} \quad (A1)$$

$$\Sigma'_y = \begin{bmatrix} 0 & -i & 0 & 0 & 0 & 0 & 0 & 0 \\ i & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & \frac{1}{\sqrt{3}} & 0 & 0 & -i\frac{\sqrt{6}}{3} & 0 \\ 0 & 0 & \frac{1}{\sqrt{3}} & 0 & \frac{2}{3} & 0 & 0 & i\frac{\sqrt{2}}{3} \\ 0 & 0 & 0 & \frac{2}{3} & 0 & \frac{1}{\sqrt{3}} & i\frac{\sqrt{2}}{3} & 0 \\ 0 & 0 & 0 & 0 & \frac{1}{\sqrt{3}} & 0 & 0 & -i\frac{\sqrt{6}}{3} \\ 0 & 0 & \frac{\sqrt{6}}{3}i & 0 & -\frac{\sqrt{2}}{3}i & 0 & 0 & \frac{1}{3} \\ 0 & 0 & 0 & -\frac{\sqrt{2}}{3}i & 0 & \frac{\sqrt{6}}{3}i & \frac{1}{3} & 0 \end{bmatrix} \quad (A2)$$

$$\Sigma'_z = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & \frac{1}{3} & 0 & 0 & i\frac{2\sqrt{2}}{3} & 0 \\ 0 & 0 & 0 & 0 & -\frac{1}{3} & 0 & 0 & -i\frac{2\sqrt{2}}{3} \\ 0 & 0 & 0 & 0 & 0 & -1 & 0 & 0 \\ 0 & 0 & 0 & -\frac{2\sqrt{2}}{3}i & 0 & 0 & -\frac{1}{3} & 0 \\ 0 & 0 & 0 & 0 & \frac{2\sqrt{2}}{3}i & 0 & 0 & \frac{1}{3} \end{bmatrix} \quad (A3)$$

Note that the set of basis functions we used are a little different from the basis used in Ref. 42, so the form of spin matrices (A1)-(A3) are different from these in Ref. 42. Using Eq. (11), we can transform $\Sigma'_x, \Sigma'_y, \Sigma'_z$ into $\Sigma_x(\varphi), \Sigma_y(\varphi), \Sigma_z(\varphi)$, which are the components of eight-band spin matrices in the new basis set. $\Sigma_x(\varphi), \Sigma_y(\varphi), \Sigma_z(\varphi)$ can be written as

$$\Sigma_x(\varphi) = \begin{bmatrix} \mathcal{B} \sin \varphi & iC \cos \varphi \\ -iC^T \cos \varphi & \mathcal{D} \sin \varphi \end{bmatrix}, \quad (\text{A4})$$

$$\Sigma_y(\varphi) = \begin{bmatrix} -\mathcal{B} \cos \varphi & iC \sin \varphi \\ -iC^T \sin \varphi & -\mathcal{D} \cos \varphi \end{bmatrix}, \quad (\text{A5})$$

$$\Sigma_z(\varphi) = \begin{bmatrix} 0 & \mathcal{F} \\ \mathcal{F} & 0 \end{bmatrix}, \quad (\text{A6})$$

where $\mathcal{B}, C, \mathcal{D}, \mathcal{F}$ are 4×4 matrices

$$\begin{aligned} \mathcal{B} &= \begin{bmatrix} -1 & 0 & 0 & 0 \\ 0 & 0 & -\frac{1}{\sqrt{3}} & -\frac{\sqrt{6}}{3} \\ 0 & -\frac{1}{\sqrt{3}} & -\frac{2}{3} & \frac{\sqrt{2}}{3} \\ 0 & -\frac{\sqrt{6}}{3} & \frac{\sqrt{2}}{3} & -\frac{1}{3} \end{bmatrix}, \quad C = \begin{bmatrix} -1 & 0 & 0 & 0 \\ 0 & 0 & \frac{1}{\sqrt{3}} & \frac{\sqrt{6}}{3} \\ 0 & -\frac{1}{\sqrt{3}} & -\frac{2}{3} & \frac{\sqrt{2}}{3} \\ 0 & -\frac{\sqrt{6}}{3} & \frac{\sqrt{2}}{3} & -\frac{1}{3} \end{bmatrix}, \\ \mathcal{D} &= \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & -\frac{1}{\sqrt{3}} & -\frac{\sqrt{6}}{3} \\ 0 & -\frac{1}{\sqrt{3}} & \frac{2}{3} & -\frac{\sqrt{2}}{3} \\ 0 & -\frac{\sqrt{6}}{3} & -\frac{\sqrt{2}}{3} & \frac{1}{3} \end{bmatrix}, \quad \mathcal{F} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & \frac{1}{3} & -\frac{2\sqrt{2}}{3} \\ 0 & 0 & -\frac{2\sqrt{2}}{3} & -\frac{1}{3} \end{bmatrix}. \end{aligned} \quad (\text{A7})$$

For a pure “spin-down” state $|\Psi_{s,-}(k_{\parallel})\rangle$, the expectation value of $\Sigma_x(\varphi), \Sigma_y(\varphi), \Sigma_z(\varphi)$ can be evaluated by

$$\langle \Sigma_x(\mathbf{k}_{\parallel}) \rangle_{s,-} = \langle \Psi_{s,-}(k_{\parallel}) | \Sigma_x(\varphi) | \Psi_{s,-}(k_{\parallel}) \rangle = \langle \mathcal{B}(k_{\parallel}) \rangle_{s,-} \sin \varphi, \quad (\text{A8a})$$

$$\langle \Sigma_y(\mathbf{k}_{\parallel}) \rangle_{s,-} = \langle \Psi_{s,-}(k_{\parallel}) | \Sigma_y(\varphi) | \Psi_{s,-}(k_{\parallel}) \rangle = -\langle \mathcal{B}(k_{\parallel}) \rangle_{s,-} \cos \varphi, \quad (\text{A8b})$$

$$\langle \Sigma_z(\mathbf{k}_{\parallel}) \rangle_{s,-} = \langle \Psi_{s,-}(k_{\parallel}) | \Sigma_z(\varphi) | \Psi_{s,-}(k_{\parallel}) \rangle = 0. \quad (\text{A8c})$$

Similarly, for a pure “spin-up” state $|\Psi_{s,+}(k_{\parallel})\rangle$, the expectation value of $\Sigma_x(\varphi), \Sigma_y(\varphi), \Sigma_z(\varphi)$ are

$$\langle \Sigma_x(\mathbf{k}_{\parallel}) \rangle_{s,+} = \langle \Psi_{s,+}(k_{\parallel}) | \Sigma_x(\varphi) | \Psi_{s,+}(k_{\parallel}) \rangle = \langle \mathcal{D}(k_{\parallel}) \rangle_{s,+} \sin \varphi, \quad (\text{A9a})$$

$$\langle \Sigma_y(\mathbf{k}_{\parallel}) \rangle_{s,+} = \langle \Psi_{s,+}(k_{\parallel}) | \Sigma_y(\varphi) | \Psi_{s,+}(k_{\parallel}) \rangle = -\langle \mathcal{D}(k_{\parallel}) \rangle_{s,+} \cos \varphi, \quad (\text{A9b})$$

$$\langle \Sigma_z(\mathbf{k}_{\parallel}) \rangle_{s,+} = \langle \Psi_{s,+}(k_{\parallel}) | \Sigma_z(\varphi) | \Psi_{s,+}(k_{\parallel}) \rangle = 0. \quad (\text{A9c})$$

According to Eqs. (A8a)-(A9c), one can easily find $\mathbf{k}_{\parallel} \cdot \langle \Sigma(\mathbf{k}_{\parallel}) \rangle_{s,\pm} = 0$. Therefore, for pure “spin-up” states or “spin-down” states, the spin orientations are in xy plane, and strictly perpendicular to the in-plane wave vector.

 - ³⁴ The exact position of Fermi level in an undoped InAs/GaSb QW should locate inside the mini gap^{3,28}. The slight difference between our calculated E_F and the exact value comes from the summation of s in Eqs. (7) and (8) not running over all subbands in our calculation.
